Transdermal Drug Delivery System:
Transdermal drug delivery is defined as self contained, discrete dosage forms which, when applied to the intact skin, deliver the drug, through the skin at controlled rate to the systemic circulation. Transdermal drug delivery system (TDDS) established itself as an integral part of novel drug delivery systems 28.

OTFs are polymeric films designed to deliver therapeutic moieties into the oral cavity or the gastrointestinal (GI) tract, where they are absorbed and routed to the circulatory system directly. As such, OTFs can rapidly deliver hydrophilic as well as hydrophobic active compounds. There are two main types of OTFs – oromucosal and orodispersible.

to be advantageous over any other novel drug-delivery systems (NDDS). An oral drug delivery system is thus believed to provide continuous oral release of the drug throughout the course of its gastrointestinal (GI) transit (Chein, 1991). The bioavailability issues are one of the major challenges for formulation research and development.

The oral route of administration is central for the delivery of a large number of important drugs in various therapeutic areas, and many patients prefer standard oral dosage forms as well as advanced oral drug delivery systems over other dosage forms. This preference stems from various factors including the non-invasiveness, ease-of-use, and reliability of oral dosage forms.
